  - ...
  - ...
ISO 9223-9226

Corrosion of metals and alloys — Corrosivity of atmospheres — Classification, determination and estimation
Present and revised version

• Existing standards 9223-9226 are the most important standards in atmospheric corrosion
• At present revised versions are prepared but it will take 1-2 years before they are issued.
• Present presentation focus on the new standards under development but the classification system is similar. Differences will be pointed out
Scope

- To establish a classification system
- Specifies the key factors in the atmospheric corrosion of metals and alloys
- Does not characterize the corrosivity of specific service atmospheres, e.g. atmospheres in chemical or metallurgical industries
- The classified corrosivity categories and introduced pollution levels can be directly used for technical and economical analyses of corrosion damage and for a rational choice of corrosion protection measures
Classification of atmospheric corrosivity, determination and estimation (ISO 9223)

Corrosivity determination based on one-year corrosion losses measured with standard metal specimens

Corrosivity estimation based on environmental information

Normative corrosivity estimation based in calculated corrosion losses for standard metals (ISO 9223)

Informative corrosivity estimation derived from comparison of exposure situation with description of typical atmospheric environments (ISO 9223)

Corrosivity categories C1 – C5 (ISO 9223)

Determination of corrosion loss on standard specimens (ISO 9226)

Measurement of environmental parameters affecting atmospheric corrosivity (ISO 9225)

Guiding values of corrosion rate for each category for specific metals (ISO 9224)

</tbody>
</table>

### NOTES

1. The classification criterion is based on the methods of determination of corrosion rates of standard specimens for the evaluation of corrosivity (see ISO 9226)
2. The corrosion rates expressed in grams per square metre year [g/(m$^2$.a)] have been recalculated in micrometres per year (μm/a) and rounded.
3. The materials are characterized in ISO 9226.
4. Aluminium experiences localized corrosion but the corrosion rates shown in the Table 2 were calculated as uniform corrosion. Maximum pit depth is a better indicator of potential damage, but this characteristic cannot be evaluated after the first year of exposure excepting the effects in corrosivity category CX.
5. Corrosion rates exceeding the upper limits in category C5 are considered as extreme. Corrosivity category CX refers to marine and marine/industrial environments.
Corrosivity estimation based on calculated one year corrosion losses

- Dose response functions for calculation of the year corrosion loss of structural metals
  - Carbon steel
  - Zinc
  - Copper
  - Aluminium
- This method is new and not employed in the present existing ISO standards
Parameters used in dose-response functions

Informative Annexes (new)

• Annex A: Atmospheric corrosivity derivation and estimation. Sources of uncertainties
• Annex B: Characterization of the atmosphere in relation to its corrosivity
• Annex C: Description of typical atmospheric environments related to the estimation of corrosivity categories
<table>
<thead>
<tr>
<th>Corrosivity category (C)</th>
<th>Corrosivity</th>
<th>Typical environments (examples)</th>
<th>Outdoor</th>
</tr>
</thead>
<tbody>
<tr>
<td>C1</td>
<td>Very low</td>
<td>Indoor: Heated spaces with low relative humidity and insignificant pollution e.g. offices, schools, museums</td>
<td>Outdoor: Dry or cold zone, atmospheric environment with very low pollution and time of wetness, e.g. certain deserts, central Antarctica</td>
</tr>
<tr>
<td>C2</td>
<td>Low</td>
<td>Indoor: Unheated spaces with varying temperature and relative humidity. Low frequency of condensation and low pollution, e.g. storage, sport halls</td>
<td>Outdoor: Temperate zone, atmospheric environment with low pollution (SO$_2$ &lt; 5 µg/m$^3$), e.g.: rural areas, small towns</td>
</tr>
<tr>
<td>C3</td>
<td>Medium</td>
<td>Indoor: Spaces with moderate frequency of condensation and moderate pollution from production process, e.g. food-processing plants, laundries, breweries, dairies</td>
<td>Outdoor: Temperate zone, atmospheric environment with medium pollution (SO$_2$: 5 µg/m$^3$ to 30 µg/m$^3$) or some effect of chlorides, e.g. urban areas, coastal areas with low deposition of chlorides</td>
</tr>
<tr>
<td>C4</td>
<td>High</td>
<td>Indoor: Spaces with high frequency of condensation and high pollution from production process, e.g. industrial processing plants, swimming pools</td>
<td>Outdoor: Temperate zone, atmospheric environment with high pollution (SO$_2$: 30 µg/m$^3$ to 90 µg/m$^3$) or substantial effect of chlorides, e.g. polluted urban areas, industrial areas, coastal areas, without spray of salt water, strong effect of de-icing salts</td>
</tr>
<tr>
<td>C5-CX</td>
<td>Very high - extreme</td>
<td>Indoor: Spaces with almost permanent condensation and/or with high pollution from production process, e.g. mines, caverns for industrial purposes, unventilated sheds in humid tropical zones</td>
<td>Outdoor: Temperate zone, atmospheric environment with very high pollution (SO$_2$: 90 µg/m$^3$ to 250 µg/m$^3$) and/or strong effect of chlorides, e.g. industrial areas, coastal and off shore areas, with salt spray</td>
</tr>
</tbody>
</table>

**NOTE 1** Deposition of chlorides in coastal areas is strongly dependent on the variables influencing the transport inland of sea-salt, such as wind direction, wind velocity, local topography, wind sheltering islands outside the coast, distance of the site from the sea, etc.

**NOTE 2** Extreme effect by chlorides, which is typical of marine splash or very heavy salt spray, as well as areas close to the coast in hot humid climates, are beyond the scope of this International Standard.

**NOTE 3** Sheltered surfaces in marine atmospheric environment where chlorides are deposited can experience a higher corrosivity category due to the presence of hygroscopic salts.

**NOTE 4** In environments with expected CX category is recommended to determine the corrosivity from one-year corrosion losses.

**NOTE 5** The concentration of sulphur dioxide (SO$_2$) should be determined during at least 1 year and is expressed as the annual average.

**NOTE 6** Detailed description of types of indoor environments within corrosivity categories C1 and C2 is given in ISO 11844-1. Indoor corrosivity categories IC1 to IC5 are distinguished...
ISO 9223 Guiding values for the corrosivity categories

• The corrosion rate of metals and alloys exposed to natural outdoor atmospheres is not constant with exposure time. For most metals and alloys it decreases with exposure time because of the accumulation of corrosion products on the surface of the metal exposed. The progress of attack on engineering metals and alloys is usually observed to be linear when the total damage is plotted against exposure time on logarithmic coordinates. This relationship indicates that the total damage expressed either as penetration depth or mass loss per unit area, “D”, may be expressed as:

\[ D = At^b \]

• Where “t” is the exposure time in years, “A” is the damage experienced in the first year, and “b” is the metal-environment specific time exponent, usually less than one; the slope of the log D versus log t plot.
### Time exponent values (b values)

- The B1 values were taken as the average time exponents from regression analyses of flat panel long-term results.
- The B2 values include two standard deviation additions and may be used where an upper limit of corrosion damage is desired.
ISO 11844

Classification of low corrosivity of indoor atmospheres
Materials

• Normative
  – Silver
  – Copper
  – Zinc
  – Carbon steel
• Informative (several other metals)
ISO 11844 Classification of low corrosivity of indoor atmospheres
  - Part 1: Determination and estimation of indoor corrosivity
  - Part 2: Determination of corrosion attack in indoor atmospheres
  - Part 3: Measurement of environmental parameters affecting indoor corrosivity
Part 3: Environmental measurements

• Climate
  – Temperature
  – Relative humidity

• Airborne gas contaminants
  – Continuous gas concentration measuring instruments
  – Average gas concentration with active sampler and air pump
  – Average gas concentration with passive sampler
  – Average gas deposition equipment

• Airborne particle contaminants
  – Concentration measurements
  – Deposition measurements
Part 3, Annex A (informative)

- Reagents used for both passive and active samplers
  - Sulphur dioxide (SO$_2$)
  - Nitrogen dioxide (NO$_2$)
  - Dihydrogen sulphide (H$_2$S)
  - Ammonia (NH$_3$)
  - Ozone (O$_3$)
  - Formic acid (HCOOH)
  - Acetic acid (CH$_3$COOH)
Part 2: Corrosion measurements

- Materials and sample preparation
- Exposure of specimens
- Evaluation of corrosion attack
  - Mass increase and mass loss (Annex A, normative)
  - Electrolytic cathodic reduction (Annex B, normative)
  - Resistance measurements (Annex C, informative)
Part 2, unsheltered exposure
Part 2, sheltered exposure
Annex A: Determination of corrosion rate by mass change measurements

- Determination of mass increase (MI)
  \[ MI = \text{Mass after exposure} - \text{Mass before exposure} \]

- Determination of mass loss (ML)
  \[ ML = \text{Mass before exposure} - \text{Mass after pickling} \]

Recommended pickling solutions included in standard

Mass increase (MI) and mass loss (ML) intervals given for silver, copper, zinc and carbon steel
Annex A: Relation between ISO, IEC and ISA classification systems

The figure shows the relation between the classification systems of ISO, IEC, and ISA. The mass increase is given in mg / (m².a) on a log scale. The classification systems are compared in the following manner:

- **ISO 9223**:
  - IC 1
  - IC 2
  - IC 3
  - IC 4
  - IC 5

- **IEC 654-4 App. B**:
  - Class 1
  - Class 2
  - Class 3

- **ISA S71.04-1985**:
  - C1
  - C2
  - C3
  - C4
  - C5

- **Not covered by this standard**:
  - G1
  - G2
  - G3
  - GX

The figure indicates that certain classes and classifications are not covered by this standard.
Annex B: Outdoor/indoor concentration of some of the most important pollutants in different types of environments

- SO$_2$
- NO$_2$
- O$_3$
- H$_2$S
- Cl$_2$
- Cl$^-$
- NH$_3$
- Organic components (acids, aldehydes)
- Particles (dust deposits)
- Soot
Annex C: General characterization of metal corrosion in indoor atmospheres

- Steel
- Zinc
- Copper
- Silver
- Nickel
- Lead
- Tin
- Aluminium
- Gold
- Stainless steel
Annex D: Guideline for estimation of indoor corrosivity

General description, temperature, relative humidity, pollution and estimation:

<table>
<thead>
<tr>
<th>Corrosivity category (IC)</th>
<th>Corrosivity</th>
<th>Typical environments</th>
</tr>
</thead>
</table>
| IC 1                     | very low indoor   | **Heated spaces** with controlled stable relative humidity (< 40 %) without risk of condensation, low levels of pollutants, no specific pollutants, e.g. computer rooms, museums with controlled environment  
Unheated spaces with dehumidification, low levels of indoor pollution, no specific pollutants e.g. military stores for equipment |
| IC 2                     | low indoor        | **Heated spaces** with low relative humidity (< 50 %) with certain fluctuation of relative humidity without risk of condensation, low levels of pollution, without specific pollutants e.g. museums, control rooms  
Unheated spaces with only temperature and humidity changes, with no risk of condensation, low levels of pollution without specific pollutants, e.g. storage rooms with low frequency of temperature changes |
| IC 3                     | medium indoor     | **Heated spaces** with risk of fluctuation of temperature and humidity, medium levels of pollution, certain risk for specific pollutants, e.g. switch boards in power industry  
Unheated spaces with elevated relative humidity (> 50 % - 70 %) with periodic fluctuation of relative humidity, without risk of condensation, elevated levels of pollution, low risk of specific pollutants, e.g. churches in non-polluted areas, outdoor telecommunication boxes in rural areas |
| IC 4                     | high indoor       | **Heated spaces** with fluctuation of humidity and temperature, elevated levels of pollution including specific pollutants, e.g. electrical service rooms in industrial plants  
Unheated spaces with high relative humidity (> 70 %) with some risk of condensation, medium levels of pollution, possible effect of specific pollutants, e.g. churches in polluted areas, outdoor boxes for telecommunication in polluted areas |
| IC 5                     | very high indoor  | **Heated spaces** with limited influence of relative humidity, higher levels of pollution including specific pollutants like H₂S, e.g. electrical service rooms, cross connection rooms in industries without efficient pollution control  
Unheated spaces with high relative humidity and risk for condensation, medium and higher levels of pollution, e.g. storage rooms in basements in polluted areas |
